

ELEC 3035, Lecture 2:

State space and polynomial representations

Ivan Markovsky

- Dynamical systems and their representations
- Linear time-invariant systems
- Input/output and input/state/output representations
- Non-uniqueness of the representations

Set notation

- $\mathcal{B} = \{w^1, \dots, w^N\}$ — the set consisting of the elements w^1, \dots, w^N
- $\mathcal{B} = \{w \mid f(w) = 0\}$ — the set of all w that satisfy $f(w) = 0$
- $w \in \mathcal{B}$ — w is an element of the set \mathcal{B}

What is a model?

Classic problem: Fit the points

$$w_1 = \begin{bmatrix} -2 \\ -6 \end{bmatrix}, w_2 = \begin{bmatrix} -1 \\ -1 \end{bmatrix}, \dots, w_5 = \begin{bmatrix} 2 \\ 4 \end{bmatrix}$$

by a line passing through the origin.

Classic solution: Define $w_i =: \text{col}(u_i, y_i)$ and solve the least squares problem

$$\text{col}(u_1, \dots, u_5)x = \text{col}(y_1, \dots, y_5).$$

The model is the line

$$\mathcal{B} := \{ w = \text{col}(u, y) \mid ux_{\text{ls}} = y \}$$

and not the equation $ux_{\text{ls}} = y$.

Dynamical system

The set of functions (signals) $w : \mathbb{T} \rightarrow \mathbb{W}$ from \mathbb{T} to \mathbb{W} is denoted by $\mathbb{W}^{\mathbb{T}}$.

- \mathbb{W} — variable space
- $\mathbb{T} \subset \mathbb{R}$ — time axis
- $\mathbb{W}^{\mathbb{T}}$ — trajectory space

A **dynamical system** $\mathcal{B} \subset \mathbb{W}^{\mathbb{T}}$ is a set of trajectories (a behaviour).

$w \in \mathcal{B}$ means that w is a possible trajectory of the system \mathcal{B}

Note: the set definition is extremely general (and therefore abstract). For example, it is not specialized to linear time-invariant systems.

Representations of dynamical systems

Systems are often described by equations

$$f(w) = 0, \quad f : \mathbb{W}^T \rightarrow \mathbb{R}^g,$$

via **representations**

$$\mathcal{B} = \{ w \in \mathbb{W}^T \mid f(w) = 0 \}. \quad (\text{repr})$$

Note: $f(w) = 0$ is a specific but nonunique description of \mathcal{B} .

We will consider systems, which variable space is \mathbb{R}^w and time axis

- $T = \mathbb{R}$ — **continuous-time** systems, or
- $T = \mathbb{Z}$ — **discrete-time** systems.

Linear time-invariant systems

Properties of a system are defined in terms of its behaviour \mathcal{B} and are translated to equivalent statements in terms of representations.

\mathcal{B} is linear if $w, v \in \mathcal{B} \implies \alpha w + \beta v \in \mathcal{B}$, for all $\alpha, \beta \in \mathbb{R}$

Recall the shift operator $(\sigma w)(t) = w(t+1)$.

\mathcal{B} is time-invariant if $w \in \mathcal{B} \implies \sigma^t w \in \mathcal{B}$, for all t .

Input/output (I/O) partitioning

Let $\Pi \in \mathbb{R}^{w \times w}$ be a permutation matrix, and define

$$\begin{bmatrix} u \\ y \end{bmatrix} := \Pi w \quad (\text{I/O})$$

(This is just a reordering of the variables.)

The variable u is an input if the behaviour associate with u is free, i.e.,

$$\mathcal{B}_u := \{ u \in (\mathbb{R}^m)^{\mathbb{T}} \mid \text{there is } y \text{ such that } \Pi^{-1} \begin{bmatrix} u \\ y \end{bmatrix} \in \mathcal{B} \} = (\mathbb{R}^m)^{\mathbb{T}}.$$

(I/O) is an I/O partitioning for \mathcal{B} if u is free and $\dim(u)$ is maximal.

We will consider systems with given I/O partition and w.l.g. assume that

$$\Pi = I.$$

Difference equations

The difference equation

$$R_0 w(t) + R_1 w(t+1) + \dots + R_\ell w(t+\ell) = 0, \quad \text{for all } t \in \mathbb{Z}$$

is more compactly written using the shift operator σ as

$$R_0 \sigma^0 w + R_1 \sigma^1 w + \dots + R_\ell \sigma^\ell w = 0. \quad (*)$$

Define the polynomial matrix

$$R(z) = R_0 + R_1 z + \dots + R_\ell z^\ell \in \mathbb{R}^{g \times w}[z]$$

and note that

$$R(\sigma)w = 0$$

is a convenient short hand notation for (*).

Differential equations

The differential equation

$$R_0 \frac{d^0}{dt^0} w + R_1 \frac{d^1}{dt^1} w + \cdots + R_\ell \frac{d^\ell}{dt^\ell} w = 0$$

is more compactly written as

$$R \left(\frac{d}{dt} \right) w = 0,$$

where again R is the polynomial matrix

$$R(z) = R_0 + R_1 z + \cdots + R_\ell z^\ell.$$

For continuous-time systems, redefine σ as the derivative operator d/dt , so $R(\sigma)w = 0$ is a difference/differential eqn., depending on the context.

Input/output representation

The difference (in discrete-time) or differential (in continuous-time) eqn

$$P(\sigma)y = Q(\sigma)u, \quad P \in \mathbb{R}^{g \times p}[z], \quad Q \in \mathbb{R}^{g \times m}[z] \quad (\text{I/O eqn})$$

defines an LTI system \mathcal{B} via

$$\mathcal{B}_{\text{i/o}}(\mathbf{P}, \mathbf{Q}) := \{ w = (u, y) \in (\mathbb{R}^w)^{\mathbb{N}} \mid (\text{I/O eqn}) \text{ holds} \} \quad (\text{I/O repr})$$

If $g = p$ and $\det(P) \neq 0$, (I/O repr) is called an input/output repr.

The class of system that admit (I/O repr) is called **finite dimensional**.

Transfer function

Consider a system $\mathcal{B}_{i/o}(P, Q)$ and let \mathcal{L} be the Laplace transform.

$$P\left(\frac{d}{dt}\right)y = Q\left(\frac{d}{dt}\right)u \quad \Longrightarrow \quad P(s)Y(s) = Q(s)U(s)$$

where $Y := \mathcal{L}(y)$ and $U := \mathcal{L}(u)$.

The rational function

$$Y(s)U^{-1}(s) = P^{-1}(s)Q(s) =: H(s)$$

is called transfer function.

In the SISO case

$$\frac{Y(s)}{U(s)} = \frac{Q(s)}{P(s)} =: h(s).$$

State of the system

- a system \mathcal{B} ,

Given

- a “past” trajectory of \mathcal{B} , $(\dots w_p(-2), w_p(-1))$, and
- a “future” input $u_f = (u_f(0), u_f(1), \dots)$

find the future output y_f of \mathcal{B} , such that

$$w := (\dots, w_p(-2), w_p(-1), w_f(0), w_f(1), \dots)$$

is a trajectory of \mathcal{B} .

It turns out that for $\mathcal{B} = \mathcal{B}_{i/o}(p, q)$, it isn't necessary to know the whole (infinite) past w_p in order to find y_f !

Suffices to know a finite dimensional, so called “state”, vector $x(0)$ of \mathcal{B} .

Input/state/output (I/S/O) representation

A finite dimensional LTI system $\mathcal{B} \in \mathcal{L}^w$ admits a representation

$$\mathcal{B}_{i/s/o}(A, B, C, D) := \{ w := \text{col}(u, y) \in (\mathbb{R}^w)^{\mathbb{N}} \mid \exists x \in (\mathbb{R}^n)^{\mathbb{N}}, \\ \text{such that } \sigma x = Ax + Bu, y = Cx + Du \}. \quad (\text{I/S/O repr})$$

- x — an auxiliary variable called **state**
- $n := \dim(x)$ — **state dimension**, \mathbb{R}^n — **state space**
- $A \in \mathbb{R}^{n \times n}$, $B \in \mathbb{R}^{n \times m}$, $C \in \mathbb{R}^{p \times n}$, $D \in \mathbb{R}^{p \times m}$ — **parameters of \mathcal{B}**
- $m := \dim(u)$ — **input dimension**, $p := \dim(y)$ — **output dimension**

single input single output (**SISO**) systems — $\dim(u) = \dim(y) = 1$

multi input multi output (**MIMO**) systems — $\dim(u) \geq 1, \dim(y) \geq 1$

- A — state transition matrix, B — input matrix
 - C — output matrix, D — feedthrough matrix
 - $\sigma x = Ax + Bu$ — state equation
 - $y = Cx + Du$ — output equation
-
- A shows how $x(t+1)$ depends on $x(t)$ (state transition)
 - B shows how $u(t)$ influences $x(t+1)$
 - C shows how $y(t)$ depends on $x(t)$
 - D shows how $u(t)$ influences $y(t)$ (static I/O relation)

Trivial extension: A, B, C, D functions of t leads to time-varying system

Comparison between I/O and I/S/O representations

- (I/S/O repr) is **first order in x and zeroth order in w**
- (I/O repr) has no auxiliary variable and is for **higher order in w**

If the system is single output,

- (I/S/O repr) is **vector difference/differential equation**
- (I/O repr) is a **scalar difference/differential equation**

We will consider the problems of constructing I/S/O repr from an I/O one and vice verse, *i.e.*,

$$(P, Q) \mapsto (A, B, C, D) \quad \text{and} \quad (A, B, C, D) \mapsto (P, Q)$$

Nonuniqueness of an I/S/O representation

There are two sources of nonuniqueness of (I/S/O repr):

1. **redundant states** — $n := \dim(x)$ bigger than “necessary”
2. **nonuniqueness of A, B, C, D** — choice of state space basis

minimal I/S/O representations — $\dim(x)$ is as small as possible

For any nonsingular matrix $T \in \mathbb{R}^{n \times n}$ and

$$\tilde{A} = T^{-1}AT, \quad \tilde{B} = T^{-1}B, \quad \tilde{C} = CT, \quad \tilde{D} = D$$

we have that

$$\mathcal{B}_{i/s/o}(A, B, C, D) = \mathcal{B}_{i/s/o}(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D}).$$

Change of state space basis

Consider an LTI system $\mathcal{B} = \mathcal{B}_{i/s/o}(A, B, C, D)$.

For any $(u, y) \in \mathcal{B}$, there is x , such that

$$\sigma x = Ax + Bu, \quad y = Cx + Du. \quad (**)$$

Let $\tilde{x} = T^{-1}x$, where $T \in \mathbb{R}^{n \times n}$ is nonsingular, so that $x = T\tilde{x}$.

Substituting in (**) and multiplying the first equation by T , we obtain

$$\sigma \tilde{x} = \underbrace{T^{-1}AT}_{\tilde{A}} \tilde{x} + \underbrace{T^{-1}B}_{\tilde{B}} u, \quad y = \underbrace{CT}_{\tilde{C}} \tilde{x} + \underbrace{D}_{\tilde{D}} u.$$

$x = T\tilde{x}$, with T nonsingular, means **change of basis in \mathbb{R}^n** (from I to T).

Nonuniqueness of an I/O representation

There are two sources of nonuniqueness of (I/O repr):

1. **redundant equations** — $g := \text{row dim}(P)$ bigger than “necessary”
2. **nonuniqueness of P, Q** — equivalence of equations

minimal I/O representations — $\text{row dim}(P)$ is as small as possible

In the single output case, P, Q are unique up to a scaling factor, *i.e.*,

$$\tilde{P} = \alpha P, \quad \tilde{Q} = \alpha Q, \quad \text{for } \alpha \in \mathbb{R}$$

we have that

$$\mathcal{B}_{i/o}(P, Q) = \mathcal{B}_{i/o}(\tilde{P}, \tilde{Q}).$$

For multi output systems the nonuniqueness of P, Q is more essential.

I/S/O \mapsto transfer function

The transfer function corresponding to a system $\mathcal{B}_{i/s/o}(A, B, C, D)$ is

$$H(s) = C(sI - A)^{-1}B + D.$$

With $X := \mathcal{L}(x)$, $Y := \mathcal{L}(y)$, $U := \mathcal{L}(u)$, we have

$$\begin{aligned}\sigma x &= Ax + Bu &\implies & sX = AX + BU \\ y &= Cx + Du &\implies & Y = CX + DU\end{aligned}$$

The first equation implies

$$(sI - A)X = BU \implies X = (sI - A)^{-1}BU.$$

Substitute in the second equation to get

$$Y = C(sI - A)^{-1}BU + DU = \underbrace{(C(sI - A)^{-1}B + D)}_{H(s)}U$$
