

Lecture 2: Numerical linear algebra

- QR factorization
- Eigenvalue decomposition
- Singular value decomposition
- Conditioning of a problem
- Floating point arithmetic and stability of an algorithm

Orthonormal set of vectors

Consider a finite set of vectors $\mathcal{Q} := \{q_1, \dots, q_k\} \subset \mathbb{R}^n$

- \mathcal{Q} is **normalized** : $\iff \|q_i\| = 1, i = 1, \dots, k$
- \mathcal{Q} is **orthogonal** : $\iff q_i \perp q_j$, for all $i \neq j$
- \mathcal{Q} is **orthonormal** : $\iff \mathcal{Q}$ is orthogonal and normalized

with $Q := [q_1 \ \dots \ q_k]$, **\mathcal{Q} orthonormal $\iff Q^\top Q = I_k$**

Properties:

- **orthonormal vectors are independent** (show this)
- multiplication with Q **preserves norm**, $\|Qz\|^2 = z^\top Q^\top Qz = \|z\|^2$
- multiplication with Q **preserves inner product**, $\langle Qz, Qy \rangle = \langle z, y \rangle$

Orthogonal projectors

Consider an orthonormal matrix $Q \in \mathbb{R}^{n \times k}$ and $\mathcal{L} := \text{span}(Q) \subseteq \mathbb{R}^n$.

The columns of Q form an **orthonormal basis** for \mathcal{L} .

$Q^\top Q = I_k$, however, for $k < n$, $QQ^\top \neq I_n$.

$\Pi_{\text{span}(Q)} := QQ^\top$ is an **orthogonal projector on $\text{span}(Q)$** , i.e.,

$$\Pi_{\mathcal{L}} x = \arg \min_y \|x - y\|_2 \quad \text{subject to } y \in \mathcal{L}$$

Properties: $\Pi = \Pi^2$, $\Pi = \Pi^\top$ (necessary and sufficient for Π orth. proj.)

$\Pi^\perp := (I - \Pi)$ is also an orth. proj., it projects on

$(\text{span}(\Pi))^\perp \subseteq \mathbb{R}^n$ — the orthogonal complement of $\text{span}(\Pi)$

Orthonormal basis for \mathbb{R}^n

orthonormal set $\mathcal{Q} := \{q_1, \dots, q_k\} \subset \mathbb{R}^n$ of $k = n$ vectors

then $Q := [q_1 \ \dots \ q_n]$ is called **orthogonal** and satisfies $Q^\top Q = I_n$

It follows that $Q^{-1} = Q^\top$ and

$$QQ^\top = \sum_{i=1}^n q_i q_i^\top = I_n$$

Expansion in orthonormal basis $x = QQ^\top x$

- $a := Q^\top x$ coordinates of x in the basis \mathcal{Q}
- $x = Qa$ reconstruct x from the coordinates a

Geometrically **multiplication by Q (and Q^\top) is rotation.**

Gram-Schmidt (G-S) procedure

Given independent set $\{a_1, \dots, a_k\} \subset \mathbb{R}^n$, G-S produces orthonormal set $\{q_1, \dots, q_k\} \subset \mathbb{R}^n$ such that

$$\text{span}(a_1, \dots, a_r) = \text{span}(q_1, \dots, q_r), \quad \text{for all } r \leq k$$

G-S procedure: Let $q_1 := a_1 / \|a_1\|$. At the i th step $i = 2, \dots, k$

- **orthogonalized** a_i w.r.t. q_1, \dots, q_{i-1} :

$$v_i := \underbrace{(I - \Pi_{\text{span}(q_1, \dots, q_{i-1})})a_i}_{\text{projection of } a_i \text{ on } (\text{span}(q_1, \dots, q_{i-1}))^\perp}$$

- **normalize** the result: $q_i := v_i / \|v_i\|$

(A modified version of the G-S procedure is used in practice.)

Navigation icons

If $\{a_1, \dots, a_k\}$ are dependent, $v_i := (I - \Pi_{\text{span}(q_1, \dots, q_{i-1})})a_i = 0$ for some i
Conversely, if $v_i = 0$ for some i , a_i is linearly dependent on $\{a_1, \dots, a_{i-1}\}$

Modified G-S procedure: when $v_i = 0$, skip to the next input vector a_{i+1}

\Rightarrow **R is in upper staircase form, e.g.,**

$$\begin{bmatrix} \times & \times & \times & \times & \times & \times & \times \\ & \times & \times & \times & \times & \times & \times \\ & & \times & \times & \times & \times & \times \\ & & & & \times & & \times \end{bmatrix} \quad \begin{array}{l} \text{(empty elements} \\ \text{are zeros)} \end{array}$$

Which vectors a_i are dependent on $\{a_1, \dots, a_{i-1}\}$ in this example?

Navigation icons

QR factorization

G-S procedure gives as a byproduct scalars r_{ji} , $j \leq i$, $i = 1, \dots, k$, s.t.

$$\begin{aligned} a_i &= (q_1^\top a_i)q_1 + \dots + (q_{i-1}^\top a_i)q_{i-1} + \|q_i\|q_i \\ &= r_{1i}q_1 + \dots + r_{ii}q_i \end{aligned}$$

in a matrix form **G-S produces the matrix factorization**

$$\underbrace{\begin{bmatrix} a_1 & a_2 & \dots & a_k \end{bmatrix}}_A = \underbrace{\begin{bmatrix} q_1 & q_1 & \dots & q_k \end{bmatrix}}_Q \underbrace{\begin{bmatrix} r_{11} & r_{12} & \dots & r_{1k} \\ 0 & r_{22} & \dots & r_{2k} \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \dots & 0 & r_{kk} \end{bmatrix}}_R$$

with orthonormal $Q \in \mathbb{R}^{n \times k}$ and upper triangular $R \in \mathbb{R}^{k \times k}$

Navigation icons

Full QR

$$A = \underbrace{\begin{bmatrix} Q_1 & Q_2 \end{bmatrix}}_{\text{orthogonal}} \begin{bmatrix} R_1 \\ 0 \end{bmatrix} \quad \begin{array}{ll} \text{span}(A) &= \text{span}(Q_1) \\ (\text{span}(A))^\perp &= \text{span}(Q_2) \end{array}$$

Procedure for finding Q_2 :

complete A to a full rank matrix, e.g., $A_m := [A \quad I]$, and apply G-S on A_m

In MATLAB:

» `[Q ,R] = qr(A) % full QR`

» `[Q1,R1] = qr(A,0) % reduced QR`

Navigation icons

Eigenvalue decomposition (EVD)

Suppose $\{v_1, \dots, v_n\}$ is a lin. indep. set of eigenvectors of $A \in \mathbb{R}^{n \times n}$

$$Av_i = \lambda_i v_i, \quad \text{for } i = 1, \dots, n$$

written in a matrix form, we have the **matrix factorization**

$$A \underbrace{[v_1 \ \dots \ v_n]}_V = \underbrace{[v_1 \ \dots \ v_n]}_V \underbrace{\begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_n \end{bmatrix}}_\Lambda$$

V is nonsingular, so that

$$AV = V\Lambda \implies V^{-1}AV = \Lambda$$

Three applications of EVD

- Compute matrix power A^k , more generally a fun. $f(A)$ of a matrix

$$f(A) = Vf(\Lambda)V^{-1} \quad (\text{assuming } A \text{ diagonalizable})$$

Example:

$$\begin{bmatrix} 1/3 & 1 \\ 0 & 1/2 \end{bmatrix}^{100} = ?$$

Three applications of EVD

- Compute matrix power A^k , more generally a fun. $f(A)$ of a matrix

$$f(A) = Vf(\Lambda)V^{-1} \quad (\text{assuming } A \text{ diagonalizable})$$

Example:

$$\begin{bmatrix} 1/3 & 1 \\ 0 & 1/2 \end{bmatrix}^{100} = ?$$

Eigenvalues: $\lambda_1 = 1/3, \lambda_2 = 1/2$, Eigenvectors: $v_1 = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, v_2 = \begin{bmatrix} 6 \\ 1 \end{bmatrix}$

Three applications of EVD

- Compute matrix power A^k , more generally a fun. $f(A)$ of a matrix

$$f(A) = Vf(\Lambda)V^{-1} \quad (\text{assuming } A \text{ diagonalizable})$$

Example:

$$\begin{bmatrix} 1/3 & 1 \\ 0 & 1/2 \end{bmatrix}^{100} = ?$$

Eigenvalues: $\lambda_1 = 1/3, \lambda_2 = 1/2$, Eigenvectors: $v_1 = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, v_2 = \begin{bmatrix} 6 \\ 1 \end{bmatrix}$

$$\begin{bmatrix} 1/3 & 1 \\ 0 & 1/2 \end{bmatrix}^{100} = \begin{bmatrix} 1 & 6 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 3^{-100} & \\ & 2^{-100} \end{bmatrix} \begin{bmatrix} 1 & -6 \\ 0 & 1 \end{bmatrix} \approx 0$$

- First order vector linear constant coef. differential/difference eqns

$$\frac{d}{dt}x(t) = Ax(t), t \in \mathbb{R}_+ \quad \text{and} \quad x(t+1) = Ax(t), t \in \mathbb{Z}_+$$

Given $x(0) \in \mathbb{R}^n$, the equation has a unique solution x .

Qualitative properties of the set of solutions, such as, **stability**

$$x(t) \rightarrow 0 \quad \text{as} \quad t \rightarrow \infty$$

are determined by the **location of the eigenvalues of A** .

- In continuous-time: stability holds $\iff \Re \lambda_i < 0$ for all i
- In discrete-time: stability holds $\iff |\lambda_i| < 1$ for all i

Overview of eigenvalue algorithms

- the best ways of computing eigenvalues are not obvious
- bad strategy: rooting the characteristic polynomial
- the power iteration $(\frac{x}{\|x\|}, \frac{Ax}{\|Ax\|}, \frac{A^2x}{\|A^2x\|}, \dots)$ is not effective in general
- modern general purpose algorithms are based on **eigenvalue revealing factorizations**
- two stages: **Hessenberg form** (finite), **Schur form** (iterative)

- Principal component analysis (PCA)

given a set of vectors $\{a_1, \dots, a_n\}$,

find an orthonormal set $\{v_1, \dots, v_n\}$, such that

$$\text{span}(a_1, \dots, a_n) \approx \text{span}(v_1, \dots, v_k), \quad \text{for } k = 1, \dots, n$$

If “ \approx ” means

$$\text{maximize} \quad \left\| \underbrace{\Pi_{\text{span}(v_1, \dots, v_k)}}_{\text{projection}} \underbrace{\begin{bmatrix} a_1 & \dots & a_n \end{bmatrix}}_A \right\|_F$$

the solution $\{v_1, \dots, v_n\}$ is an orthonormal set of eigenvectors of $A^T A$ ordered according to the magnitude of the eigenvalues.

Used for data compression/recognition (eigenfaces, eigengenies, ...)

Any eigenvalue solver must be iterative

$$p(z) = p_0 + p_1 z + \dots + z^n \quad \leftrightarrow \quad A = \begin{bmatrix} -p_{n-1} & -p_{n-2} & \dots & -p_1 & -p_0 \\ 1 & 0 & \dots & 0 & 0 \\ 0 & 1 & \ddots & \vdots & \vdots \\ \vdots & \ddots & \ddots & 0 & 0 \\ 0 & \dots & 0 & 1 & 0 \end{bmatrix}$$

$$\text{roots of } p \quad \leftrightarrow \quad \text{eigenvalues of } A$$

Eigenvalue computation is a more general problem than root finding.

No analogue of quadratic formula exists for polynomials of degree ≥ 5 .
(Abel 1824)

The aim of eigenvalue solvers is to produce

sequence of numbers that converges rapidly towards eigenvalues.

Rayleigh quotient

Symmetric $A \in \mathbb{R}^{n \times n}$ has n real eigenvalues, which we index as follows

$$\lambda_{\min} := \lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_n =: \lambda_{\max}$$

Corresponding to $\lambda_1, \dots, \lambda_n$, we choose orthonormal set of eigenvectors

$$v_1, \dots, v_n$$

Rayleigh quotient of $v \in \mathbb{R}^n$ (w.r.t. A) is a mapping $r: \mathbb{R}^n \rightarrow \mathbb{R}$ defined by

$$r(v) := \frac{v^\top A v}{v^\top v}$$

Note that $r(\alpha v_i) = \lambda_i$, for all $\alpha \in \mathbb{R}$ and $i = 1, \dots, n$.

Fact: $\min_v r(v) = \lambda_{\min}$ and $\max_v r(v) = \lambda_{\max}$.

Power iteration

- **Given:** unit norm vector $v^{(0)}$ and symmetric matrix A
- For $k = 1, 2, \dots$ (till convergence)
 - Apply A : $w = Av^{(k-1)}$
 - Normalize: $v^{(k)} := w / \|w\|$
- **Output:** eigenvalue/eigenvector of A — $((v^{(k)})^\top A v^{(k)}, v^{(k)})$

If $|\lambda_1| > |\lambda_2|$ and $v_1^\top v^{(0)} \neq 0$,

$$v^{(k)} \rightarrow \pm v_1$$

with **linear convergence** rate $O(|\lambda_2/\lambda_1|)$.

Inverse iteration

- **Given:** unit norm vector $v^{(0)}$, symmetric matrix A , and $\mu \geq 0$
- For $k = 1, 2, \dots$ (till convergence)
 - Apply $(A - \mu I)^{-1}$: solve $(A - \mu I)w = v^{(k-1)}$
 - Normalize: $v^{(k)} := w / \|w\|$
- **Output:** eigenvalue/eigenvector of A — $((v^{(k)})^\top A v^{(k)}, v^{(k)})$

Let λ be the closest eigenvalue to μ and λ' be the second closest.

Let v be the unit norm eigenvector corresponding to λ . If $v^\top v^{(0)} \neq 0$,

$$v^{(k)} \rightarrow \pm v$$

with **linear convergence** rate $O(|(\mu - \lambda')/(\mu - \lambda)|)$.

Rayleigh quotient iteration

- **Given:** unit norm vector $v^{(0)}$ and symmetric matrix A
- Let $\lambda^{(0)} := (v^{(0)})^\top A v^{(0)}$
- For $k = 1, 2, \dots$ (till convergence)
 - Apply $(A - \lambda^{(k-1)} I)^{-1}$: solve $(A - \lambda^{(k-1)} I)w = v^{(k-1)}$
 - Normalize: $v^{(k)} := w / \|w\|$
 - Let $\lambda^{(k)} := (v^{(k)})^\top A v^{(k)}$
- **Output:** eigenvalue/eigenvector of A — $(\lambda^{(k)}, v^{(k)})$

Let λ be the closest eigenvalue to μ and v be the corresponding eigenvector. If $v^\top v^{(0)} \neq 0$,

$$v^{(k)} \rightarrow \pm v \quad \text{with cubic convergence rate.}$$

Exercise

- Implement the power, inverse power, and Rayleigh quotient methods
- Apply them on examples and observe their convergence properties
- Comment on the results

Simultaneous power iteration

Take a set of initial vectors $\{v_1^{(0)}, \dots, v_p^{(0)}\}$ and consider the iteration:

$$\underbrace{\begin{bmatrix} v_1^{(k+1)} & \dots & v_p^{(k+1)} \end{bmatrix}}_{V^{(k+1)}} = A \underbrace{\begin{bmatrix} v_1^{(k)} & \dots & v_p^{(k)} \end{bmatrix}}_{V^{(k)}}, \quad k = 0, 1, \dots$$

One can expect that under suitable assumptions

$$\text{span}(v_1^{(k)}, \dots, v_p^{(k)}) \rightarrow \text{span}(v_1, \dots, v_p), \quad \text{as } k \rightarrow \infty$$

However,

$$v_i^{(k)} \rightarrow v_1, \quad \text{as } k \rightarrow \infty, \quad \text{for all } i$$

so $V^{(k+1)}$ becomes increasingly **ill-conditioned** as $k \rightarrow \infty$.

Normalized simultaneous power iteration

- **Given:** orthonormal matrix $Q^{(0)} \in \mathbb{R}^{n \times p}$ and symmetric matrix A
- For $k = 1, 2, \dots$ (till convergence)
- Apply A : solve $Z = AQ^{(k-1)}$
- Compute orthonormal basis for $\text{image}(Z)$:

$$\text{QR factorization: } Q^{(k)} R^{(k)} = Z$$

- **Output:** orthonormal eigenvectors of A — $Q^{(k)}$

Under suitable assumptions

$$\text{image}(Q^{(k)}) \rightarrow \text{span}(v_1, \dots, v_p), \quad \text{as } k \rightarrow \infty.$$

Hessenberg and Schur forms

Every square matrix has a Hessenberg form

$$A = Q \underbrace{\begin{bmatrix} \times & \times & \dots & \times & \times \\ \times & \times & \dots & \times & \times \\ & \times & \ddots & \ddots & \times \\ & & \ddots & \ddots & \vdots \\ & & & \times & \times \end{bmatrix}}_H Q^\top$$

Q — orthogonal
 H — upper Hessenberg

and a Schur form

$$A = UTU^\top \quad \begin{array}{l} U \text{ — unitary (complex orthogonal)} \\ T \text{ — upper triangular} \end{array}$$

In MATLAB: `[Q,H] = hess(A), [U,T] = schur(A)`
`[V,L] = eig(A)`

QR algorithm

The basic QR algorithm is normalized simultaneous power iteration with a full set $p = n$ vectors and initial condition $Q^{(0)} = I_n$.

- **Given:** a symmetric matrix $A^{(0)} = A$
- For $k = 1, 2, \dots$ (till convergence)
- QR factorization: $A^{(k-1)} = Q^{(k)} R^{(k)}$
- Recombine in reverse order: $A^{(k)} = R^{(k)} Q^{(k)}$
- **Output:** a Schur decomposition of A — $Q^{(k)}, R^{(k)}$.

$$A^{(k)} = R^{(k)} Q^{(k)} = Q^{(k)\top} A^{(k-1)} Q^{(k)} \implies A^{(k)} \text{ is similar to } A^{(k-1)}$$

Additional features of a practical QR algorithm

- **Pre-processing:** reduce A to tridiagonal form before the iteration
- **Shifts:** factor $A^{(k)} - \lambda^{(k)} I$, $\lambda^{(k)}$ — eigenvalue estimate
- **Deflations:** reduce the size of A when an eigenvalue is found

QR algorithm with shifts \leftrightarrow Rayleigh quotient iteration

Generalized eigenvalues

Consider $n \times n$ matrices A and B ; the pair (A, B) is called **pencil**

(v, λ) is a generalized eigenvector/eigenvalue of the pencil (A, B) if

$$Av = \lambda Bv$$

For nonsingular B , the generalized eigenvalue problem is equivalent to

$$B^{-1}Av = \lambda v$$

standard eigenvalue problem

Generalized Rayleigh quotient:

$$\lambda_{\min} = \min_{v \in \mathbb{R}^n} \frac{v^\top Av}{v^\top Bv}, \quad \lambda_{\max} = \max_{v \in \mathbb{R}^n} \frac{v^\top Av}{v^\top Bv}$$

Singular value decomposition

The SVD is used as both computational and analytical tool.

Any $m \times n$ matrix A has an SVD

$$A = \underbrace{[u_1 \ \dots \ u_r]}_U \underbrace{\begin{bmatrix} \sigma_1 & & \\ & \ddots & \\ & & \sigma_r \end{bmatrix}}_\Sigma \underbrace{[v_1 \ \dots \ v_r]^\top}_{V^\top}$$

where U and V are orthonormal

- $\sigma_1, \dots, \sigma_r$ are called **singular values**
- u_1, \dots, u_r are called **left singular vectors**
- v_1, \dots, v_r are called **right singular vectors**

Geometric fact motivating the SVD

The image of a unit ball under linear map is a hyperellips.

$$\underbrace{\begin{bmatrix} 1.00 & 1.50 \\ 0 & 1.00 \end{bmatrix}}_A = \underbrace{\begin{bmatrix} 0.89 & -0.45 \\ 0.45 & 0.89 \end{bmatrix}}_U \underbrace{\begin{bmatrix} 2.00 & 0 \\ 0 & 0.50 \end{bmatrix}}_\Sigma \underbrace{\begin{bmatrix} 0.45 & -0.89 \\ 0.89 & 0.45 \end{bmatrix}}_{V^T}$$

Full SVD

Reduced SVD of a matrix $A \in \mathbb{R}^{m \times n}$ of rank r

$$A = U_1 \Sigma_1 U_1^T = [u_1 \ \cdots \ u_r] \begin{bmatrix} \sigma_1 & & \\ & \ddots & \\ & & \sigma_r \end{bmatrix} \begin{bmatrix} v_1^T \\ \vdots \\ v_r^T \end{bmatrix}$$

Full SVD: find $U_2 \in \mathbb{R}^{m \times (m-r)}$ and $V_2 \in \mathbb{R}^{n \times (n-r)}$ such that

$$U := [U_1 \ U_2] \quad \text{and} \quad V := [V_1 \ V_2] \quad \text{are orthogonal}$$

and add zero rows/columns to Σ_1 to form $\Sigma \in \mathbb{R}^{m \times n}$

Warning: The singular values are $\sigma_1, \dots, \sigma_r$ plus $\min(m-r, n-r)$ zeros

In MATLAB: $[U, S, V] = \text{svd}(A)$ — full SVD
 $[U, S, V] = \text{svd}(A, 0)$ — reduced SVD

Link between SVD and EVD

- both SVD and EVD diagonalize a matrix A
 - left singular vectors of A are eigenvectors of AA^T
 - right singular vectors of A are eigenvectors of $A^T A$
 - the nonzero singular values of A are the square roots of the nonzero eigenvalues of AA^T or $A^T A$
- Q: What are the eigenvalues of $\begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$?
- for a symmetric A , $|\lambda_i| = \sigma_i$

Differences between SVD and EVD

- SVD exists for **any matrix**
 EVD exist for **some square matrices**
- SVD applies **two orthogonal similarity transformations**
 EVD applies **one** (in general not orthonormal) similarity transf.
- EVD is useful in problems where **A is repeatedly applied**
 SVD is used to analyse a **single application of A** on a vector

Conditioning of a problem

Problem: $f: \mathcal{X} \rightarrow \mathcal{Y}$, where \mathcal{X} is the data space
 \mathcal{Y} is the solutions space

Usually f is a continuous nonlinear function.

Consider a particular data instance $X_0 \in \mathcal{X}$.

The problem f is called **well conditioned** at the data X_0 if

small perturbations in X lead to small changes in $f(X)$

Absolute condition number: $\lim_{\delta \rightarrow 0} \sup_{\|\tilde{X}\| < \delta} \frac{\|f(X_0 + \tilde{X}) - f(X_0)\|}{\|\tilde{X}\|}$

Relative condition number: $\lim_{\delta \rightarrow 0} \sup_{\|\tilde{X}\| < \delta} \frac{\|f(X_0 + \tilde{X}) - f(X_0)\| / \|f(X_0)\|}{\|\tilde{X}\| / \|X_0\|}$

Navigation icons

Conditioning of root finding

Given polynomial coefficients $\{p_0, p_1, \dots, p_n\}$, find its roots $\{\lambda_1, \dots, \lambda_n\}$

$$p(\lambda) = p_0 + p_1 \lambda^1 + \dots + p_n \lambda^n = c(\lambda - \lambda_1) \dots (\lambda - \lambda_n)$$

The relative condition number of λ_j w.r.t. perturbation \tilde{a}_i of a_i is

$$\kappa_{i,j} = |a_i \lambda_j^{i-1}| / \left| \frac{d}{d\lambda} p(\lambda_j) \right|$$

Example: For $p(\lambda) = \Pi_1^{20}(\lambda - i)$, $\arg \max_{i,j} \kappa_{i,j} = (15, 15)$

```
» roots(poly([1:20]))
ans = 1.0000 ... 14.0684 14.9319 16.0509 ... 20.0003
```

Check the computed roots of $(\lambda - 1)^4$ (`roots(poly([1 1 1 1]))`).

Navigation icons

Condition number of matrix–vector product

Theorem: The problem of computing $y = Ax$, given nonsingular matrix $A \in \mathbb{R}^{n \times n}$ and $x \in \mathbb{R}^n$ has relative cond. number w.r.t. perturbations in x

$$\kappa = \|A\| \frac{\|x\|}{\|y\|} \leq \|A\| \|A^{-1}\|$$

Condition number of a matrix: $\kappa(A) := \|A\| \|A^{-1}\|$

for nonsquare matrices and 2-norm $\|\cdot\|$, $\kappa(A) := \sigma_{\max}(A) / \sigma_{\min}(A)$

A is **ill-conditioned** if $\kappa(A)$ is large, A is **well-conditioned** if $\kappa(A)$ is small

$\kappa(A)$ is related to perturbations in the worst case

For an ill-conditioned A , $y = Ax$ may be well-conditioned, for certain x

Navigation icons

Condition number of solving systems of equations

Theorem: The problem of computing $x = A^{-1}y$, given $A \in \mathbb{R}^{n \times n}$ and $y \in \mathbb{R}^n$ has relative cond. number $\kappa(A)$ w.r.t. perturbations in A .

Proof: The perturbation \tilde{A} in A leads to a perturbation \tilde{x} in x , such that

$$(A + \tilde{A})(x + \tilde{x}) = y \implies \tilde{A}x + A\tilde{x} \stackrel{1}{=} 0$$

“ $\stackrel{1}{=}$ ” means equal up to first order terms in \tilde{A} and \tilde{x} .

($\kappa(A)$ describes the effect of infinitesimal perturbations.)

$$\begin{aligned} \tilde{x} \stackrel{1}{=} -A^{-1}\tilde{A}x &\implies \|\tilde{x}\| \leq \|A^{-1}\| \|\tilde{A}\| \|x\| \\ &\implies \frac{\|\tilde{x}\| / \|x\|}{\|\tilde{A}\| / \|A\|} \leq \|A^{-1}\| \|A\| = \kappa(A) \quad \square \end{aligned}$$

Navigation icons

Digital representation of real numbers

IEEE double precision arithmetic:

- **Range:** $[-2.23 \times 10^{-308}, 1.79 \times 10^{308}]$ **overflow/underflow**
- **Discretization:** $[2^i, 2^{i+1}] \mapsto 2^i \{1, 1 + 2^{-52}, 1 + 2 \times 2^{-52}, \dots, 2\}$

The gaps between adjacent numbers are in a relative scale at most

$$\varepsilon := 2^{-52} \approx 2.22 \times 10^{-16} \quad \text{machine precision}$$

- **fixed point:** the position of the decimal point is fixed
- **floating point:** its position is stored together with the digits

fixed point leads to uniform absolute errors

floating point leads to **uniform relative errors**

Rounding: let $\text{fl}(x)$ be the digital representation of $x \in \mathbb{R}$, $|\text{fl}(x) - x| \leq \varepsilon$

Stability of an algorithm

Problem: $f: \mathcal{X} \rightarrow \mathcal{Y}$, **Algorithm:** $\hat{f}: \mathcal{X} \rightarrow \mathcal{Y}$

\hat{f} is backward stable if for each $X \in \mathcal{X}$ there is $\hat{X} \in \mathcal{X}$, such that

$$\frac{\|X - \hat{X}\|}{\|X\|} = O(\varepsilon) \quad \text{and} \quad \hat{f}(X) = f(\hat{X})$$

in words:

backward stable algorithm gives the right answer to a nearby problem

$e(\tilde{X}) := \|\tilde{X}\|/\|X\| = O(\varepsilon)$ means that there is $c, \delta > 0$ such that

$$\|\tilde{X}\| < \delta \quad \implies \quad |e(\tilde{X})| \leq c\varepsilon$$

Computational complexity of an algorithm

measured by # of flops (floating point operations) or execution time

1 flop — one addition, subtraction, multiplication, or division

the flops count is usually simplified to leading order terms, e.g., $O(n)$

useful in theoretical comparison of algorithms but it is not an accurate predictor of the computation time

- n vector–vector operations — $O(n)$ flops
e.g., vector sum, scalar–vector multiplication, inner product
- $m \times n$ matrix–vector product — $O(mn)$ flops
- $m \times n$ matrix – $n \times p$ matrix product — $O(mnp)$ flops

Example: solving $Ax = b$ with general $A \in \mathbb{R}^{n \times n}$ requires $O(n^3)$ flops

Linear equations with special structure

- **diagonal** — n flops ($x_i = y_i/a_{ii}$ for $i = 1, \dots, n$)
- **lower/upper triangular**: n^2 flops (via forward/backward substitution)
- **banded** — $O(nk)$, where k is the bandwidth
- **symmetric** — $O(n^3/3)$ (via Cholesky decomposition)
- **orthogonal** — $O(n^2)$ ($x = A^T y$)
- **permutation** — 0 flops
- **Toeplitz** — $O(n^2)$ flops
- combination of banded, symmetric, and Toeplitz

Numerical linear algebra software

Matlab uses as its computational kernel LAPACK

LAPACK is a freely available FORTRAN library
currently the state-of-the-art software for numerical linear algebra

MATLAB provides simple and convenient interface to LAPACK
it is an excellent tool for research; free alternatives to MATLAB are

- octave
- scilab

BLAS and LAPACK

- **BLAS** — Basic Linear Algebra Subroutines, and
ATLAS — Automatically Tunable Linear Algebra Subroutines
 - Level 1 BLAS: vector–vector operations
 - Level 2 BLAS: matrix–vector products
 - Level 3 BLAS: matrix–matrix products
- **LAPACK** — Linear Algebra PACKage
 - Matrix factorizations; exploit triangular, banded, diagonal structures
 - Solvers for linear systems, LS, LN problems; provide error bounds

ScaLAPACK — version for parallel computers.
