# Software for approximate linear system identification

 Markovsky, J. C. Willems, S. Van Huffel, and B. De Moor K.U.Leuven, ESAT/SCD (SISTA)

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005

#### Discrete-time LTI systems

LTI system:  $\mathscr{B} \subset (\mathbb{R}^q)^{\mathbb{Z}}$ , *i.e.*, a set of q-variables time-series  $w : \mathbb{Z} \to \mathbb{R}^q$  $\mathscr{L}^q$  — class of finite dimensional LTI systems with q variables

input/state/output representation of  $\mathscr{B} \in \mathscr{L}^q$ 

$$w = \begin{bmatrix} u \\ y \end{bmatrix}, \qquad x(t+1) = Ax(t) + Bu(t) \\ y(t) = Cx(t) + Du(t)$$
 (I/S/O)

*m* — number of inputs

p — number of outputs (invariant of the representation)

m — minimal state dimension

#### **Outline**

- Discrete-time linear time-invariant (LTI) systems
- Approximate LTI system identification
- Examples
  - approximate realization
  - identification from step response data
  - autonomous system identification
  - model reduction

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2009

#### Discrete-time LTI systems

difference equation representation of  $\mathscr{B} \in \mathscr{L}^q$ 

$$R_0 w(t) + R_1 w(t+1) + \dots + R_l w(t+l) = 0$$
 (DE)

the smallest possible l is called the lag of  $\mathcal{B}$  (also invariant)

 $\dim(\mathcal{B})$  — complexity of the system, specified by (m,n) or (m,l)

 $\mathscr{L}_{m,l}^q$  — model class of LTI systems of bounded complexity (# inputs  $\leq m$ , lag  $\leq l$ )

### **Approximate LTI system identification**

the quality of fit of  $w_d \in (\mathbb{R}^q)^T$  ("d" for data) by the model  $\mathscr{B} \in \mathscr{L}^q$  is measured by the  $\ell_2$ -distance from  $w_d$  to  $\mathscr{B}$ 

$$M(w_{\mathrm{d}},\mathscr{B}) := \min_{\hat{w} \in \mathscr{B}} \|w_{\mathrm{d}} - \hat{w}\|_{\ell_2}$$

 $M(w_d, \mathcal{B})$  is called misfit (lack of fit) between  $w_d$  and  $\mathcal{B}$ 

global total least squares problem

$$\hat{\mathscr{B}} := \arg\min_{\mathscr{B} \in \mathscr{L}^q_{m,l}} M(w_{\mathrm{d}}, \mathscr{B}) \tag{GTLS}$$

4

misfit minimization over LTI models of bounded complexity

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005

#### **Solution** approach

block-Hankel matrix constructed from  $w = (w(1), \dots, w(T))$ 

$$\mathcal{H}_{l+1}(w) := \begin{bmatrix} w(1) & w(2) & \cdots & w(T-l) \\ w(2) & w(3) & \cdots & w(T-l+1) \\ \vdots & \vdots & & \vdots \\ w(l+1) & w(l+2) & \cdots & w(T) \end{bmatrix}$$

generically equivalent formulation of (GTLS):

$$\hat{X} = \arg\min_{X} \left( \min_{\hat{w}} \| w_{\mathsf{d}} - \hat{w} \|_{\ell_{2}}^{2} \quad \text{s.t.} \quad \mathscr{H}_{l+1}^{\top}(\hat{w}) \begin{bmatrix} X \\ -I_{p} \end{bmatrix} = 0 \right) \quad (\mathsf{STLS})$$

known as structured total least squares problem

$$egin{bmatrix} \hat{X}^ op & -I \end{bmatrix} = egin{bmatrix} \hat{R}_0 & \hat{R}_1 & \cdots & \hat{R}_l \end{bmatrix}, \qquad ext{diff. eqn. repr. of } \hat{\mathscr{B}}$$

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005

#### 5

#### **Software**

ident:  $(w_d, m, l) \mapsto (\hat{A}, \hat{B}, \hat{C}, \hat{D})$  solves (GTLS) misfit:  $(w_d, (A, B, C, D)) \mapsto (M, \hat{w}_d)$  misfit computation

calling syntax:

[ sysh, info, wh, xini ] = ident( w, m, 1, options )
[ M, wh, xini ] = misfit( w, sys, options )

- multiple given time series  $w_k = (w_k(1), \dots, w_k(T))$  can be treated
- elements of w can be specified as "exact", in which case they are not modified in the approximation  $\hat{w}$

### Example l = 0: Approximation by a static model

with l = 0, GTLS  $\equiv$  classical total least squares (TLS)

```
>> 1 = 0; m = 2; p = 3; T = 20; >> info
                                info =
>> % Generate data
                                    iter: 1
        = 1*p:
                                    time: 0
>> sys0 = drss_(n,p,m);
                                       M: 1.5838e-16
>> u0 = randn(T,m);
                                >>
>> y0 = lsim(sys0,u0);
                                >> % Verify the results
>> w0 = [u0 v0];
                                >> err_sys = norm(sys0 - sysh)
>> w = w0:
                                err_sys = 0
                                >> err_w = norm(w0 - wh,'fro')
>> % Identify the system
                                err w =
>> [sysh,info,wh]=ident(w,m,1);
```

#### **Example: Exact data**

```
if the data is exact, \hat{\mathscr{B}} \equiv \text{data generating system } \bar{\mathscr{B}}
>> 1 = 2; m = 2; p = 2; T = 100; >> info
                                     info =
>> % Generate data
                                          iter: 1
>> n = 1*p:
                                          time: 0.0200
>> sys0 = drss_(n,p,m);
                                             M: 1.8817e-15
>> u0 = randn(T.m):
                                     >>
>> v0 = lsim(sys0,u0);
                                     >> % Verify the results
>> w0 = [u0 v0]:
                                     >> err_sys = norm(sys0 - sysh)
>> w = w0:
                                     err_{sys} = 2.4896e-15
                                     >> err w = norm(w0 - wh. 'fro')
>>
>> % Identify the system
                                     err w = 2.0814e-15
>> [sysh,info,wh]=ident(w,m,1);
```

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005

#### **Example:** Errors-in-variables system identification

in the EIV setup

```
w_{\mathrm{d}} = \bar{w} + \tilde{w}, \quad \text{where} \quad \bar{w} \in \bar{\mathcal{B}} \in \mathcal{L}_{m,l}^q, \quad \tilde{w} \sim \mathrm{N}(0, \bar{\sigma}^2 I)  (EIV)
```

the GTLS solution is a maximum likelihood estimator

```
>> % Perturb the "true" data w0 with noise
>> w = w0 + 0.5 * randn(T,m+p);
>> % Identify the system
>> [sysh,info,wh] = ident(w,m,1);
>> info = iter: 100 time: 1.0100 M: 6.7320
>> % Verify the results
>> err_data = norm(w0-w,'fro')/norm(w0,'fro')
err_data = 0.2605
>> err_appr = norm(w0-wh,'fro')/norm(w0,'fro')
err_appr = 0.1963
```

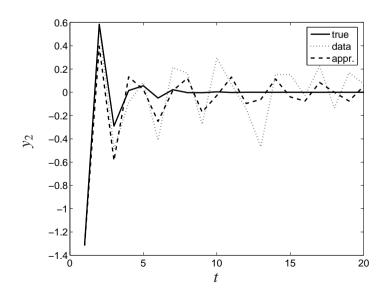

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005

#### 9

### **Example** m = 0: **Output-only identification**

```
>> % Generate data
         = 20; % length of the data sequence
>> T
>> xini0 = randn(n,1);
>> v0
         = initial(sys0,xini0,T);
         = y0:
>> w0
>> % Perturb the "true" data w0 with noise
\gg w = w0 + 0.25 * randn(T,p); % given data
>>
>> % Identify the system
\Rightarrow [sysh,info,wh] = ident(w,0,1);
>> info iter: 100 time: 0.1500 M: 1.0719
>>
>> % Verify the results
>> err_data = norm(w0-w,'fro')/norm(w0,'fro')
err_data =
              0.7269
>> err_appr = norm(w0-wh,'fro')/norm(w0,'fro')
err_appr =
              0.4184
```

#### **Example** m = 0: **Output-only identification**

10

#### Example: Identification from step response data $s_{\rm d}$

a priori known zero initial conditions and pulse inputs

```
M(s_{\rm d},\mathscr{B})=\min\|s_{\rm d}-\hat{s}\|_{\ell_2} subject to \hat{s} is a step response of \mathscr{B} multi-input systems \leadsto multiple (equal length) time series \Longrightarrow % Generate data \Longrightarrow T = 150; % length of the data sequence \Longrightarrow y0 = step(sys0,T);
```

>> 
% Construct the inputs

>> u0 = zeros(T,m,m);

>> y = y0 + 0.25 \* randn(T,p,m);

>> for i = 1:m, u0(:,i,i) = ones(T,1); end >> w = [u0 y]; % input/output data

>> % Perturb the "true" data y0 with noise

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005

12

14

```
>> % Precede it with 1 zeros
>> wext = [zeros(1.m+p.m): w]:
>>
>> % Identify the system from the ext. data
>> opt.exct = [1:m]; % exact inputs
>> [sysh,info,whext] = ident(wext,m,l,opt);
>> info
info =
    iter: 100
    time: 3.2200
       M: 5.9504
>> wh = whext(l+1:end,:,:); % Remove the trailing part
>> % Verify the results
>> w0 = [u0 v0]:
>> err_data = norm(w0(:)-w(:))/norm(w0(:))
err data =
             0.1711
>> err_appr = norm(w0(:)-wh(:))/norm(w0(:))
err_appr =
             0.0384
```

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005

13

## Example: Identification from impulse response data $h_{ m d}$

identification from exact impulse response — (partial) realization theory approximation — Kung's algorithm, we will consider misfit minimization  $M(h_{\rm d},\mathscr{B})=\min\|h_{\rm d}-\hat{h}\|_{\ell_2}\quad \text{subject to}\quad \hat{h} \text{ is an impulse response of } \mathscr{B}$ 

direct approach: I/O ident. with exactly known ini. cond. and input indirect approach: — an equivalent output only-identification problem the impulse response of (I/S/O) is equal to the free responses of

$$x(t+1) = Ax(t), y(t) = Cx(t) (AUT)$$

under initial conditions—the columns of B

```
>> % Generate data
>> T = 50; % length of the data sequence
>> y0 = impulse(sys0,T);
>> % Perturb the "true" data y0 with noise
>> y = y0 + 0.25 * randn(T,p,m);
>>
>> % Solution 1: I/O identification.
>> u0 = zeros(T,m,m); u0(1,:,:) = eye(m); % Construct the inputs
>> w = [u0 y]; % given input/output data
>> wext = [zeros(1,m+p,m); w]; % Precede w with 1 zeros
>>
>> % Identify the system from the ext. data
>> opt.exct = [1:m]; % exact input
>> [sysh1,info1,whext] = ident(wext,m,l,opt);
>> info1 = iter: 100 time: 1.1300 M: 3.4258
>> wh1 = whext(l+1:end,:,:); % Remove the trailing part
>> % Solution 2: output-only identification.
>>
```

```
>> % Identify an autonomous system
>> [sysh2,info2,yh2,xini2] = ident(y(2:end,:,:),0,1);
\Rightarrow yh2 = [y(1,:,:); yh2];
>> info2 = iter: 100 time: 0.6300 M: 3.3443
>>
>> % Recover the I/O system
>> sysh2 = ss(sysh2.a,xini2,sysh2.c, reshape(yh2(1,:,:),p,m),-1);
>> wh2 = [u0 yh2];
>> % Verify the results
>> w0 = [u0 v0];
>> err_data = norm(w0(:)-w(:))/norm(w0(:))
err_data =
               0.9219
>> err_appr1 = norm(w0(:)-wh1(:))/norm(w0(:))
err appr1 =
               0.2716
>> err_appr2 = norm(w0(:)-wh2(:))/norm(w0(:))
err_appr2 =
               0.2608
```

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005

16

#### Example: Finite time $\ell_2$ model reduction

finite time T,  $\ell_2$  norm of  $\mathscr{B}$ 

$$\|\mathscr{B}\|_{\ell_2,T} := \|h|_{[0,T]}\|_{\ell_2} = \sqrt{\sum_{t=0}^T \|h(t)\|_{\mathrm{F}}^2}.$$

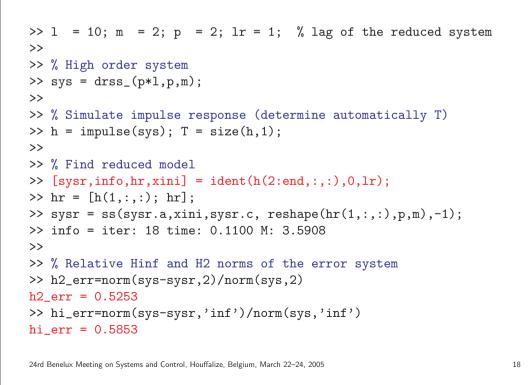

for a strictly stable system  $\mathscr{B}$ ,  $\|\mathscr{B}\|_{\ell_2,\infty} = \|\mathscr{B}\|_{\mathscr{H}_2}$ 

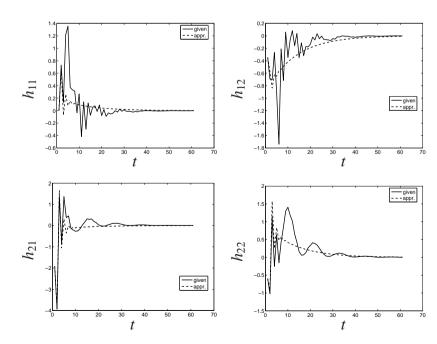

#### problem:

Given a system  $\bar{\mathcal{B}} \in \mathcal{L}^q_{m,l}$ , a natural number  $l_{\text{red}} < l$ , and a time horizon T, find a system  $\hat{\mathcal{B}} \in \mathcal{L}^q_{m,l_{\text{red}}}$ , that minimizes the finite time T,  $\ell_2$  norm  $\|\bar{\mathcal{B}} - \hat{\mathcal{B}}\|_{\ell_2,T}$  of the error system.

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005

17

## Example: The optimal misfit is generically independent of the input/output partitioning

for an arbitrary permutation matrix  $\Pi \in \mathbb{R}^{q \times q}$ 

$$\min_{\mathscr{B}\in\mathscr{L}^q_{m,l}}M(w_{\mathrm{d}},\mathscr{B})=\min_{\mathscr{B}\in\mathscr{L}^q_{m,l}}M(\overline{\mathsf{\Pi}}w_{\mathrm{d}},\mathscr{B})$$

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005

#### **Conclusions**

- the STLS problem allows to treat a variety of problems
  - approximate realization
  - identification from step response data
  - autonomous system identification
  - model reduction

20

- the common framework is misfit minimization
- current research: relation to the classical prediction error methods

24rd Benelux Meeting on Systems and Control, Houffalize, Belgium, March 22-24, 2005
